1 Analytical (15 points)

1) (15 points) The probability density function of most Markov Random Fields cannot be factorized as the product of a few conditional probabilities. This question explores some MRFs that can be factorized in this way.

Consider the graph structure in Figure 1. From this graph, we know that X_2 and X_3 are conditionally

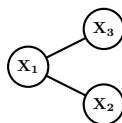

Figure 1: The Original Undirected Graph

independent given X_1 . We can draw the corresponding directed graph as Figure 2. This suggests the following

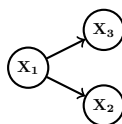

Figure 2: The Converted Directed Graph

factorization of the joint probability:

$$P(X_1, X_2, X_3) = P(X_3|X_1)P(X_2|X_1)P(X_1)$$

Now consider the following graphical model in Figure 3.

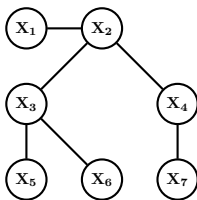

Figure 3: An Undirected Graph

As before, we can read the conditional independence relations from the graph.

(a) Following the example above, write a factorization of the joint distribution:

$$P(X_1, X_2, X_3, X_4, X_5, X_6, X_7).$$

- (b) Is this factorization unique, meaning, could you have written other factorizations that correspond this model? If the factorization is unique, explain why it is unique. If it is not unique, provide an alternate factorization.
- (c) What is it about these examples that allows them to be factored in this way? Show an example MRF that cannot be factored in this way.
